Possible Prophylaxes of Aloe Vera Juice with CoQ₁₀ to Enhance Muscle Performance

Akira Yagi, Suzuka Ataka

Coenzyme Q (CoQ₁₀) is a major antioxidant principle found in human body which plays a vital role in maintaining several biochemical pathways of body. Deficiency of CoQ₁₀ in body leads to several potential disorders in oxido-reductive reactions of electron transport chain. Present review offers preliminary insight into using dietary supplements, aloe vera juice with CoQ₁₀, to support and optimize quality of life in the people suffering from muscle performance. A questionnaire on aloe vera juice with CoQ₁₀ supplement was given to adult subjects. The questionnaire included 10 points regarding their mental, circulatory, and muscular functions, and the scoring was recorded from top six conditions in Table 1 and 2. Table 2 summarizes the noteworthy information of aloe vera juice with CoQ₁₀ supplement. The high molecular weight and lipophilicity of CoQ₁₀, making its poor water solubility and leading to low systemic availability, may be reduced by supplementation of aloe vera juice with CoQ₁₀. Possible prophylaxes of aloe vera juice with CoQ₁₀ supplement to enhance muscle performance are fully expected.

Key words: Aloe Vera Juice; CoQ₁₀ Supplement; Heart Failure; High Blood Pressure; Bioavailability; Exercise Ability; Questionnaire

INTRODUCTION

Coenzyme Q₁₀ (CoQ₁₀) is a substance that helps convert food into energy, and found in almost every cell in the body, having a powerful antioxidant. Scientists believe free radicals contribute to the aging process, as well as a number of health problems. For a number of years, CoQ₁₀ was known for its key role in mitochondrial bioenergetics; later studies demonstrated its presence in other subcellular fractions and in blood plasma, and extensively investigated its antioxidant role. These two functions constitute the basis for supporting the clinical use of CoQ₁₀. CoQ₁₀ deficiencies are clinically and genetically heterogeneous. This syndrome has been associated with five major clinical phenotypes: 1. encephalomyopathy, 2. severe infantile multisystemic disease, 3. cerebellar ataxia, 4. isolated myopathy, and 5. nephrotic syndrome[1]. CoQ₁₀ deficiency could result from: (1) impaired CoQ₁₀ synthesis due to nutritional deficiencies (such as vitamin B6 deficiency, a cofactor essential for CoQ₁₀ biosynthesis); (2) a genetic or acquired defect in CoQ₁₀ synthesis or utilization; or (3) increased tissue needs resulting from a particular disease. Since oral administration of CoQ₁₀ can increase tissue levels of the nutrient, it is possible to correct CoQ₁₀ deficiency and is particularly essential in the life-treating infantile encephalopathy[2]. CoQ₁₀ may enhance aerobic capacity and muscle performance making it a great supplement for athletes and people suffering fatigue.
Some researchers believe that CoQ\textsuperscript{10} supplements, either by themselves or in with other drug therapies, may help prevent or treat the following conditions: 1. heart failure, 2. high blood pressure, 3. high cholesterol, 4. diabetes, 5. improve immune functions in people with AIDS, 6. improve exercise ability in people with aninga, 7. help prevent migraines.

Present review article focuses on (1) prevention of heart failure or high blood pressure by aloe vera juice with CoQ\textsuperscript{10}; (2) the bioavailability of aloe vera juice with CoQ\textsuperscript{10}; (3) improvement of exercise ability by CoQ\textsuperscript{10} with dietary supplement, because other subjects, such as prevention of high cholesterol and diabetes immune functions etc., have been discussed in relation to aloe vera on former review articles\textsuperscript{1,4,5,9}. In addition to the main theme, a survey of a large number of adults on ingestion of aloe vera juice alone or the juice with CoQ\textsuperscript{10} supplement was comparatively conducted by filling out a questionnaire, and the results of questionnaire totaling in a large number of volunteers were summarized in Table 1 and 2. Possible prophylaxes of aloe vera juice with CoQ\textsuperscript{10} supplement to enhance muscle performance was indicated based upon the questionnaire responses.

**PREVENTION OF HEART FAILURE OR HIGH BLOOD PRESSURE BY ALOE VERA JUICE WITH COQ\textsuperscript{10}**

The cardio-excitatory effects of aloe extract on the isolated atria was demonstrated and the chemical and spectral examinations led to the conclusion that compounds I-IV, isolated from Aloe saponaria leaf pulp extract, using solvent partition, nonionic porous resin, and gel permeation chromatographies, are calcium salts of (+)-isocitric, L-(-)-malic, succinic, and of (-)-2-hydroxy- butadienoic acid 4-methyl ester, respectively. Cardiac stimulant activity of calcium (+)-isocitrate isolated and synthesized steroisomers of calcium isocitrate was demonstrated and a positive inotropic effect showed in isolated guinea pig atria at a concentration of 10\textsuperscript{-4} g/ml, only in the form of calcium salts, while no toxic effect such as arrhythmia was observed\textsuperscript{8}. Oral administration of Aloe vera leaf extract for 21 days in alloxan induced diabetic rabbits produced a significant reduction in fasting blood glucose levels and HbA1c in the study. Also there was significant decrease in serum levels of triglycerides, total cholesterol, low density lipoprotein cholesterol and a concomitant increase in high density lipoprotein cholesterol in Aloe vera treated diabetic rabbit indicates the potential of Aloe vera as anti-diabetic drug. Gupta A. group indicated that the significant decrease in atherogenic index in Aloe vera treated group shows its protection against cardio-vascular disease\textsuperscript{9}. Kumar P. group investigated the dose dependent effect of aloe vera gel on repolarization state of myocardium, heart rate, QRS complex and QT interval using electrocardiograph in albino rats. A total of 24 male albino rats were divided into four groups, one control and three experimental of six animal each. An aqueous solution of aloe vera was prepared by taking 10 g of gel from the fresh leaf of aloe plant and dissolved in 100 ml of distilled water. The heart were perfused with aqueous solution of aloe in dose of 100mg, 200mg, and 300 mg/L of Kreb’s solutions. The results showed that no significant difference in baseline heart rate and force of contraction among control and experimental groups. Aloe vera in dose of 200 mg/L and 300 mg/L of Kreb’s-Henseleit solution was intervened showed highly significant change in force of contraction and coronary flow as compared in control. The study showed that aloe vera cause increase in myocardial force of contraction and coronary flow; therefore aloe vera may be cardio protective\textsuperscript{10}. Jain N. group evaluated markers of oxidative stress in heart tissue along with the protective, antioxidant and anti-diabetic activity of 30% aloe vera gel in diabetic rats. Streptozocin was given as a single intravenous injection and 30% aloe vera gel was given in two doses for 20 days, orally. Blood glucose, glycosylated haemoglobin, blood reduced glutathione, serum lactate dehydrogenase and serum creatine kinase levels were recorded at the end of the study. Different biochemical variables were evaluated in the heart tissue, including thio-barbituric acid reactive substance (TBARS), reduced glutathione, superoxide dismutase and catalase in diabetic and in aloe vera-treated diabetic rats. In streptozocin diabetic rats, the TBARS level

Questionnaire assessment of volunteer 1283 subjects of male: 72 female: 1191 unknown: 20; age-range from 20th to 70 th old; recovery ratio: 34.85 %; in plural respondent in the total 3681, was carried out during September 27, 2014 to November 27, 2014. Two hundred ml of IASC-certified aloe vera juice with 80mg of CoQ\textsuperscript{10} powder (Forever Living Product, Japan) was orally ingested once a day for three months. Questionnaire evaluation was based on the following scheme: 1. No change, 2. Slightly better, 3. Very much better, 4. Slightly worse, 5. Very much worse. In order to fairly evaluate the juice, only responses to question No.3 were adopted as positive in each health condition. There was no adverse effect through three months trial period.
was increased significantly, superoxide dismutase and reduced glutathione significantly decreased, and the catalase level was significantly increased. Aloe vera 30% gel (200 mg/kg) treatment in diabetic rats reduced the increased TBARS and maintained the superoxide dismutase and catalase activity up to the normal level. Aloe vera gel increased reduced glutathione by four times in diabetic rats. In conclusion, aloe vera gel at 200 mg/kg had significant anti-diabetic and cardio-protective activity[10]. Drag-reducing polymers (DRP) increase tissue perfusion at constant driving pressure. Macias CA. group evaluated the effects of small-volume resuscitation with a solution containing a DRP in a rat model of hemorrhage. Anesthetized rats were hemorrhaged at a constant rate over 25 min. In protocol A, total blood loss was 2.45 mL/100g, whereas in protocol B, total blood loss was 3.15 mL/100g. Five minutes after hemorrhage, the animals were resuscitated with 7 mL/kg of either normal saline (NS) or NS containing 50 μg/mL of an aloe vera-derived DRP. In protocol B, a third group (CON) was not resuscitated. Whole-body O2 consumption (Vo2) and CO2 production (Vco2) were measured using indirect calorimetry. In protocol A, 5/10 rats in the NS group and 8/10 rats in the DRP group survived for 4 h (p < 0.14). Mean arterial pressure was higher in the DRP-treated group than in the NS-treated group 45 min after resuscitation (89 ± 8 vs. 68±5 mmHg, respectively, p < 0.05). In protocol B, survival rates over 2 h in the DRP, NS, and CON groups were 5/15, 1/14, and 0/7, respectively (p < 0.05). Compared with NS-treated rats, those resuscitated with DRP achieved a higher peak VO2 (9.0 ±1.0 vs 6.3 ±1.0 mL/kg/min) and VCO2 (9.0 ±1.1 vs 6.0 ±1.0 mL/kg/min) after resuscitation. Macias CA. group concluded that resuscitation with a small volume of DRP prolongs survival in rats with lethal hemorrhagic shock[11]. Sixteen adult male rats were anesthetized and mechanically ventilated. An i.v. infusion of either dextran-40 2.5% (control, n = 8) or dextran-40 2.5% containing 50 g/mL of an aloe vera-based DRP (DRP, n = 8) was initiated at 3.5 mL/h. The left anterior descending coronary artery was ligated. Blood pressure, skin-tissue perfusion, and heart rate were monitored and arterial blood samples were analysed. The mortality at 60 min following coronary ligation was 0% in the DRP group vs 50% in the control group (p = 0.025). DRP-treated animals maintained higher mean arterial pressure [60.9 ± 5.1 vs 47.5 ± 5.1 mmHg, p = 0.004] and tissue perfusion [4.2 ±3.4 vs 1.2 ±0.5 TPU, p = 0.029]. The DRP group tended towards better acid-base status with base excess [-5.0 ± 1.7 vs -8.1 ± 5.1 mmol/L, p = 0.083] and pH [7.42 ± 0.07 vs 7.35 ± 0.02, p = 0.03]. In conclusion, Sakai T. group showed that administration of nanomolar concentrations of aloe vera-based DRP prolonged survival time in animals with acute myocardial ischemia. DRPs may offer a novel method to treat organ/tissue hypoperfusion[12]. Lee BJ. group investigated the effects of CoQ10 supplementation on inflammatory markers (high-sensitivity C-reactive protein [hs-CRP], interleukin-6 [IL-6], and homocysteine) in patients with coronary artery disease (CAD). Patients with CAD (n = 51) were randomly assigned to a placebo group (n = 14) or one of two coenzyme Q10-supplemented groups (60 mg/d, Q1-60 group, n = 19; 150 mg/d, Q1-150 group, n = 18). The intervention was administrated for 12 wk. Plasma CoQ10 concentration, inflammatory markers (hs-CRP, IL-6, and homocysteine), malondialdehyde, and superoxide dismutase activities were measured. Forty subjects with CAD completed the intervention study. The plasma CoQ10 concentration increased significantly in the Q10-60 and Q10-150 groups (p < 0.01). After 12 wk of intervention, the inflammatory marker IL-6 (p = 0.03) was decreased significantly in the Q10-150 group. Subjects in the Q10-150 group had significantly lower malondialdehyde levels and those in the Q10-60 (p = 0.05) and Q10-150 (p = 0.06) groups had greater superoxide dismutase activities. Plasma CoQ10 was inversely correlated with hs-CRP (r = 0.20, p = 0.07) and IL-6 (r = 0.25, p = 0.03) at baseline. After supplementation, plasma CoQ10 was significantly correlated with malondialdehyde (r = -0.35, p < 0.01) and superoxide dismutase activities (r = 0.52, p < 0.01). However, there was no correlation between CoQ10 and homocysteine. In conclusion, CoQ10 supplementation at a dosage of 150mg appears to decrease the inflammatory marker IL-6 in patients with CAD[13]. Low CoQ10 level have been detected in patients with fibromyalgia (FM). Cordero MD. group assessed the effect of CoQ10 on symptoms of five patients with FM. Patients were evaluated clinically with visual analogical scale of pain (VAS), and fibromyalgia impact questionnaire (FIQ). Patients with CoQ10 deficiency showed a statistically significant reduction on symptoms after CoQ10 treatment during 9 months (300 mg/day). Determination of deficiency and consequent supplementation in FM may result in clinical improvement[14]. Tarry-Adkins JL. group demonstrated that rats exposed to a low-protein diet in utero that underwent postnatal catch-up growth (recovered) have a programmed deficit in cardiac coenzyme Q (CoQ) that was associated with accelerated cardiac aging. The authors investigated whether aortic and white blood cell (WBC) CoQ is programmed by suboptimal early nutrition and whether post-weaning dietary supplementation with CoQ could prevent programmed accelerated aging. Recuperated male rats had reduced aortic CoQ [22d (35 ± 8.4%; p < 0.05); 12m (53 ± 8.8%; p < 0.05)], accelerated aortic telomere shortening (∼p < 0.01), increased DNA damage (79 ± 13% increase in nearendonucleases-VIII-like-1), increased oxidative stress (458±67% increase in NAPDH-oxidase-4; p < 0.001), and decreased mitochondrial complex II-III activity (∼p < 0.05). Post-weaning dietary supplementation with CoQ prevented these detrimental programming effects. Recuperated WBC also had reduced CoQ (74 ± 5.8%; p < 0.05). Notably, WBC CoQ levels correlated with aortic telomere-length (∼p < 0.0001) suggesting its potential as a diagnostic marker of vascular aging. The authors concluded that early intervention with CoQ in at-risk individuals may be a cost-effective and safe way of reducing the global burden of cardiovascular-disease[15]. A systematic review of the literature was conducted by using databases including Medline, Embase, the Cochrane central register of control trials, and manual examination of references from selected studies. Studies included were randomized controlled trials of CoQ supplementation that reported the ejection fraction (EF) or New York Heart Association (NYHA) functional class as a primary outcome. Information on participant charactereristics, trial design and duration, treatment, dose, control, EF, and NYHA classification were extracted by using a standardized protocol. Fotino AD. group concluded that pooled analysis of available randomized controlled trials suggest that CoQ may improve the EF in patients with congestive heart failure. Additional well-designed studies that include more diverse populations are needed[16]. Rather N. group explored the effect of aqueous extract of Aloe vera gel on behavioural parameters of pain. Pain assessment was performed by the tail-flick and formalin tests. Aloe vera gel extract containing 3.14% aloin was dissolved in distilled water to prepare suspensions of required dose of 100 mg, 200 mg and 400 mg/kg. Aloe vera (100 mg/kg, oral) produced an insignificant decrease in the pain response in the tail-flick and formalin tests. Moreover, Aloe vera (200 and 400 mg/kg, p.o.) did not have significant effect on the tail-flick test. However, Aloe vera (200 and 400 mg/kg, p.o.) significantly decreased the second phase of the formalin-induced pain. Thus, these findings suggest that Aloe vera exerts its effect by a peripheral mechanism of action rather than central[17]. Garrido-Maraver J. group
reported that CoQ₁₀ was known for its key role in mitochondrial bioenergetics as electron and proton carrier: rate studies demonstrated its presence in other cellular membranes and in blood plasma, and extensively investigated its antioxidant role. These two functions constitute the basis for supporting the clinical indication of CoQ₁₀. Furthermore, recent data indicate that CoQ₁₀ affects expression of genes involved in human cell signalling, metabolism and transport and some of the effect of CoQ₁₀ supplementation may be due to this property. CoQ₁₀ deficiencies are due to autosomal recessive mutations, mitochondrial diseases, age-related oxidative stress and cardiogenesis processes, and also a secondary effect of statin treatment. Many neurodegenerative disorders, diabetes, cancer, fibromyalgia, muscular and cardiovascular diseases have been associated with low CoQ₁₀ levels. CoQ₁₀ treatment does not cause serious adverse effects in humans and new informations have been developed that increase CoQ₁₀ absorption and tissue distribution. Oral CoQ₁₀ treatment is a frequent mitochondrial energizer and antioxidant strategy in many diseases that may provide a significant symptomatic benefit[222]. Five thousand patients of atheromatous heart disease, as angina pectoris, were studied by Agarwal OP, over a period of five years. After adding the ‘Husk of isabogol’ (Plantago ovata seeds) and ‘Aloe vera’ to the diet, a marked reduction in total serum cholesterol, serum triglycerides, fasting and post prandial blood sugar level in diabetic patients, total lipid and also increase in HDL were noted. Simultaneously the clinical profile of these patients showed reduction in the frequency of anginal attacks and gradually, the drugs like verapamil, nifedipine, β-blockers and nitrates, were tapered. The patients, most benefitted, were diabetic (without adding any anti-diabetic drug). The exact mechanism of the action of the above two substances is not known, but it appears, that probably they act by their high fibre contents. Both these substances need further evaluation. The most interesting aspect of the study was that no untoward side effect was noted and all the five thousand patients are surviving till date[223]. The randomized controlled multicenter trial evaluated CoQ10 as adjunctive treatment in chronic heart failure (HF) was studied by Mortensen SA. Group. A total of 420 patients were enrolled. There were no significant changes in short-term endpoints. The primary lon-term endpoint was reached by 15% of the patients in the CoQ₁₀ group vs 26% in the placebo group (hazard ratio: 0.50; 95% confidence interval: 0.32 to 0.80; p = 0.003) by intention-to-treat analysis. The following secondary endpoints were significantly lower in the CoQ₁₀ group compared with the placebo group: cardiovascular mortality (9% vs 16%, p = 0.026), all-cause mortality (10% vs 18%, p = 0.018), and incidence of hospital stays for HF (p = 0.033). In addition, a significant improvement of New York Heart Association class was found in the CoQ₁₀ group after 2 years (p = 0.028). In conclusion, long-term CoQ₁₀ treatment of patients with chronic HF is safe, improves symptoms, and reduces major adverse cardiovascular events[223]. The multicentre randomized placebo-controlled Q-SYM-BIO (randomized, placebo-controlled, double-blinded study; CoQ₁₀-symbio trial by DiNiccolantonio JI. Group) has assessed the impact of supplemental CoQ₁₀ (100mg three times daily) or placebo and were followed for 2 years. Although short-term functional endpoints were not statistically different in the two groups, CoQ₁₀ significantly reduced the primary long-term endpoint - a major adverse cardiovascular event - which was observed in 15% of the treated participants compared to 26% of those receiving placebo (HR=0.50, CI 0.32 to 0.80, p = 0.003). Particularly good results were observed in patients with previous heart failure, and merits evaluation in additional large studies[224].

The Bioavailability of CoQ₁₀ with Aloe Vera

Deficiency of CoQ₁₀ in body leads to several potential disorders like dysfunctions in cellular energetics, neurological degeneration, higher oxidative stress induced damage, breast cancer etc. The high molecular weight and lipophilicity of CoQ₁₀ makes it poorly water soluble and consequently leads to low systemic availability. Several advancements have been made to enhance the bioavailability of CoQ₁₀ using various approaches; solid dispersion and ionization, and use of novel drug carriers; liposomes and self-emulsifying system, and cyclodextrin formations.

Ranade AN. group examined the efficacy of herbal constituents by applying the concept of a novel drug delivery system, and designed to deliver and retain two herbal constituents in the stomach for better action against gastroic ulcers. The objective was to develop a bilayer floating tablet of ammonium glycerrhizin (MG) and Aloe vera gel powder through rational combination of excipients to give the lower possible lag time with maximum drug release in 7 h. Formulation of 2 containing hydroxy propyl methyl cellulose E5, crospovidone and effervescent agents in the ratio 1: 2 gave 98% drug release with desired floating properties. Pharmacodynamic studies in rats showed that the combination of MG and Aloe vera gel gave 99% ulcer inhibition in comparison with 51% ulcer inhibition in the group administered with MG alone. X-ray studies in rabbits proved the gastroretention of the tablet for more than 6 h. This suggests relevance of novel drug delivery system in delivery of herbal constituents in the treatment of gastric ulcer[225]. Pereira GG. group reported the evaluation of the polymer films containing Aloe vera and vitamin E to treat wound caused by burns. Around 30% of vitamin E acetate was released from the polymer films within 12h. The in vivo experiments with tape stripping indicated an effective accumulation in the stratum corneum when compared to a commercial cream containing the same quantity of vitamin E acetate. Vitamin E was found in higher quantities in the deep layers of the stratum corneum when the film formulation was applied. The results showed that the bioadhesive films containing vitamin E acetate and Aloe vera could be an innovative therapeutic system for the treatment of burns[226].

The high molecular weight and lipophilicity of CoQ₁₀ makes it poorly water soluble and consequently leads to low systemic availability. Several advancements have been made to enhance the bioavailability of CoQ₁₀, and as one of the solubility enhancement water suspension of CoQ₁₀ in the form of a complex with β-cyclodextrin was investigated by Zmitnek J. Group. A randomized three-period crossover clinical trial was performed in which a single dose of CoQ₁₀ was administered orally to healthy human subjects. The pharmacokinetic parameters of two forms of the novel CoQ₁₀ material were determined and compared to soft-gel capsules with CoQ₁₀ in soybean oil that acted as a reference. The mean increase of CoQ₁₀ plasma concentrations after dosing with CoQ₁₀ vital forms determined to be over the reference formulation and the area under the curve values, extrapolated to infinity, were also higher with the tested forms; statistically significant 120 and 79% increases over the reference were calculated for the CoQ₁₀ vital liquid and powder, respectively. In conclusion, the study revealed that the absorption and bioavailability of CoQ₁₀ in the novel formulations are significantly increased, probably due to the enhanced water solubility[227]. Madhavi D. group compared the relative bioavailability of CoQ₁₀-dextrin inclusion complex with
2 commercially available formulations: a hard gelatin capsule of crystalline CoQ₁₀, MicroActive CoQ₁₀ complex (5 subjects) and an oil-solubilized CoQ₁₀ softgel containing a proprietary absorption enhancer (11 subjects). All the subjects in the accumulation phase of the study showed a minimum of doubling in the plasma CoQ₁₀ levels after 21 days of MicroActive CoQ₁₀ supplementation, which represents a 100% response rate. The solubilized formulation showed a response rate of only 44%, again confirming the greater and more uniform bioavailability of MicroActive product. In conclusion, sustained release MicroActive CoQ₁₀ is more universally bioavailable, thereby improving its ability to deliver both maintenance and the therapeutic does of CoQ₁₀[27]. Bergamini C. group examined the cellular and mitochondrial ubiquinone content in two cell lines after supplementation with a hydrophilic CoQ₁₀ formulation (Qter) and native CoQ₁₀. The results showed that the water soluble formation is more efficient in increasing ubiquinone levels. The authors had evaluated the bioenergetic effect of ubiquinone treatment, demonstrating that intracellular CoQ₁₀ content after Qter supplementation positively correlates with an improved mitochondrial functionality (increased oxygen consumption rate, transmembrane potential, ATP synthesis) and resistance to oxidative stress. In conclusion, the improved cellular energy metabolism related to increase CoQ₁₀ content represents a strong rationale for the clinical use of CoQ₁₀ and highlights the biological effects of Qter, that make it the eligible CoQ₁₀ formulation for the ubiquinone supplementation[28]. Kim EA. group investigated the dispersions of CoQ₁₀ nanoparticles in aqueous solutions of a maize starch containing high amount of amylose (70g amyllose/100g starch). Aqueous dispersion of CoQ₁₀ nanoparticles could be prepared by using amyloamylase starch or its dextrin (average DP 311). CoQ₁₀ (100mg dry solids) was dispersed in aqueous starch or dextrin solution 850mg/5ml at 60-80°C for 3 days, and then the solids were isolated by centrifugating in the dispersion (25,000 x g, 30 min). The isolated particles consisted of CoQ₁₀ was confirmed under differential scanning calorimetry, but most of the CoQ₁₀ in the particles existed as crystalline aggregates. The isolated particles, initially ranged in micrometer, could be re-dispersed in water at nano-sizes by treating with a mild ultrasonication. The aqueous dispersions of CoQ₁₀ nanoparticles (100mg/100g) exhibited zeta potentials of -33.9 and -51.1 mV, respectively for starch and dextrin dispersions, and remained homogeneous for more that 3 weeks without forming precipitates during an ambient storage[27]. Yoon HK. group investigated the stabilization of aqueous dispersion of CoQ₁₀ nanoparticles using maize starches. Aqueous CoQ₁₀ dispersions were prepared by blending CoQ₁₀ (60mg) in aqueous maize starch dispersion (300mg in 30 ml water) at 60-100°C for up to 6 h. The CoQ₁₀ agglomerates were removed by centrifugation (5000 x g, 30 min) and filtration through a glass filter. As the temperature increased, the amount of CoQ₁₀ which was stably dispersed increased. Normal maize starch was more effective in dispersing the CoQ₁₀ (57.3%) than waxy (100% amylopectin content) and high-amylose (> 50% amylose content) maize starches (9.3% and 21.9%, respectively). A light scattering analysis revealed that ultra-sonication during cooling was effective in preventing the formulation of CoQ₁₀ agglomerates. The average particle size of dispersed CoQ₁₀ was < 150 nm. Differential scanning calorimetry and x-ray diffraction analysis revealed that dispersed CoQ₁₀ particles had no amylose complex crystals. The CoQ₁₀ dispersion, however, remained homogeneous without forming precipitates during ambient storage for 2 weeks[28].

**IMPROVEMENT OF EXERCISE ABILITY BY COQ₁₀**

The changes of oxidative stress and antioxidant markers in plasma after repeated bouts of supramaximal exercise and the effects of CoQ₁₀ supplementation were determined by Gul I. group. on these changes. The randomized double blind, cross-over study was composed of two 8-week periods of supplementation with either 100mg/day CoQ₁₀ or placebo. Fifteen healthy and sedentary men participated in the study. Five Wingate tests with 2 min rest between tests were performed. Blood samples were collected at rest, immediately after, 15 and 60 min after the fifth Wingate test for oxidative stress (malondialdehyde, nitric oxide, xanthine oxidase and adenosine deaminase) and anti-oxidant (superoxide dismutase, glutathione peroxidase and uric acid) markers. At baseline exercise session, malondialdehyde increased 15 and 60 min after the exercise compared to the rest and immediately after the exercise. Malondialdehyde at rest, immediately after and 60 min after the exercise decreased with CoQ₁₀ supplementation when compared to baseline. At baseline exercise session, uric acid increased 15 and 60 min after the exercise when compared to the rest. In conclusion, lipid peroxidation and antioxidant defense increase after repeated short-term supramaximal exercise. CoQ₁₀ supplementation partially prevents the increase in lipid peroxidation after repeated short-term supramaximal exercise[29]. Bloomer RJ. group reported impact of oral ubiquinol on blood oxidative stress and exercise performance. Fifteen exercise-trained individuals (10 men and 5 women; 30-65 years) received reduced CoQ₁₀ (Kaneka QH ubiquinol; 300mg/day) or a placebo for four weeks in a random order, double blind, cross-over design (3 week washout). After each four-week period, a graded exercise treadmill test and a repeated cycle sprint test were performed (separated by 48 h). Blood samples were collected before and immediately following both exercise tests and analysed for lactate, malondialdehyde, and hydrogen peroxide. Resting blood samples were analysed for CoQ₁₀ (ubiquinone and ubiquinol) profile before and after each treatment period. Treatment with CoQ₁₀ resulted in a significant increase in total blood CoQ₁₀ (138%; p = 0.02) and reduced blood CoQ₁₀ (168%; p = 0.02), but did not improve exercise performance (with the exception of selected individuals) or impact oxidative stress. The relationship between the percentage change in total blood CoQ₁₀ and the cycle sprint total work (R² = 0.6009) was noted to be moderate to strong. The authors concluded that treatment with CoQ₁₀ in healthy, exercise-trained subjects increases total and reduced blood CoQ₁₀, but this increase does not translate into improved exercise performance of decreased oxidative stress[30]. Alf D. group investigated the effect of ubiquinol supplementation on physical performance measured as maximum power output in young and healthy elite trained athletes. One hundred young German well trained athletes (53 male, 47 female, age 19.9 ± 2.3 years) received either 300 mg ubiquinol or placebo for 6 weeks. Athletes had to perform a maximum power output test and the performance in W/kg of body weight was measured at the 4 mmol lactate threshold on a cycling ergometer before the supplementation treatment (T1), after 3 weeks (T2) and after 6 weeks (T3) of treatment. In these 6 weeks all athletes trained individually in preparation for the Olympic Games in London 2012. The maximum power output was measured in Watt/kilogram body weight (W/kg bw). Both groups, placebo and ubiquinol, significantly increased their physical performance measured as maximum power output over the treatment period from
T1 to T3. The placebo group increased from 3.64 ± 0.49 W/kg bw to 3.94 ± 0.47 W/kg bw which is an increased of + 0.30 ± 0.18 W/ kg bw or + 8.5 (± 5.7). The ubiquinol group increased performance levels from 3.70 W/kg bw (± 0.56) to 4.08 W/kg bw (± 0.48) from time point T1 to T3 which is an increase of +0.38± 0.22 W/kg bw or +11.0% (± 8.2). The absolute difference in the enhancement of the physical performance between the placebo and the ubiquinol group of +0.08 W/kg bw was significant (p < 0.03). In conclusion, this study demonstrates that daily supplementation of 300mg ubiquinol for 6 weeks significantly enhanced physical performance measured as maximum power output by +0.08 W/kg bw (+2.5%) versus placebo in young healthy trained German Olympic athletes. While adherence to a training regimen itself resulted in an improvement in peak power output, as observed by improvement in placebo, the effect of ubiquinol supplementation significantly enhanced peak power production in comparison to placebo [31]. Ubiquinol supplementation having a high water dispersion property, plays an important role in bioenergetic process in trained athletes.

RESPONSE OF ALOE VERA JUICE WITH COQ10 INGESTION TO CHRONIC FATIGUE SUBJECTS

The questionnaire included 10 points regarding the health conditions and the scoring was recorded from top three conditions in Table 1 and 2. Table 1 and 2 demonstrated the personal experiences on administration of aloe vera juice with and without COQ10 supplement under the agreement of the principle of the Helsinki declaration. Specially, the results in Table 2 having an available recovery ratio showed high responses in plural answer. At the end of the study, none of the subjects experienced any side effects or aggravation of health problems from aloe vera juice ingestion with COQ10 supplement. Table 1 and 2 demonstrated the noteworthy information for putative prophylaxes of aloe vera juice with COQ10 supplement to enhance muscle performance and improve exercise ability.

CONCLUSION AND FUTURE PERSPECTIVES

People with diabetes and obesity can benefit due to COQ10’s role in energy production. COQ10 may enhance aerobic capacity and muscle performance making it great supplement for people suffering chronic fatigue. Yoon HK, group reported that aqueous COQ10 dispersion could be prepared simply by physically blending COQ10 in starch (high amylose type; V-amylose complex) or its dextrin solution without adding any emulsifier. The dispersion in an aqueous maize starch or dextrin solution could be reproduced a homogeneous dispersion in water with good storage stability. The starch dispersion containing COQ10 remained stable during ambient storage for 2 weeks [29]. Using maize starch seems to be a simple and convenient way to prepare aqueous dispersion of water-insoluble particles. The transfer processes for gelatinization may be mainly influenced by free amylose for network formation.

 Nanoparticles coated with mannan were lyophilizable, and lyophilization was shown to enhance the stability of the nanoparticles. The feasibility of lyophilizing the nanoparticles and their thermal properties and the binding and uptake of the nanoparticles by a macrophages cell line were studied by Cui Z. group. Differential scanning calorimetry provided evidence that the nanoparticles were not a physical mixture of their individual components. The cell binding and uptake studies demonstrated that the nanoparticles coated with mannan, have potential application for cell-specific targeting [22].

CoQ10 nanoparticles could be lyophilized using low concentrations of disinacharides that served as cryo-protectants during lyophilization. This process was shown to increase the stability of the nanoparticles. The release profile of CoQ10 from the nanoparticles demonstrated a rapid release followed by a long period of slow release. CoQ10 nanoparticles with potential application for oral CoQ10 delivery were engineered readily from microemulsion precursors. Hsu CH, group concluded that CoQ10 nanoparticles may be considered as a promising carrier for oral delivery [33].

Present review article revealed novel and positive efficacies of aloe vera juice with CoQ10 supplement in quality of life as shown in Table 1 and 2. The demonstrated efficacies of aloe vera juice ingestion with CoQ10 supplement in Table 2, may promise greater possibility for promoting and enhancing muscle performance. Acemannan (a main water-soluble polysaccharide of Aloe vera mucilaginous gel consisting of mannose-rich β (1-4) linked-glucomannan back-bone with a Man:Glu ratio of ~15:1) may contribute, at least in part, to aqueous network formation of CoQ10 in ingestion of aloe vera juice supplement.

ACKNOWLEDGEMENTS

The authors express their deep gratitude to Forever Living Product Japan for supplying aloe vera juice and CoQ10 supplement, and totaling of questionnaire.

CONFLICT OF INTERESTS

The authors declare that they do not have conflict of interests.
